PDI = Predistribution Inversion

First step of PDI is to find the accumulation zone and then look for a IFVG once price manipulates and then get an entry to catch the distribution move

The most optimal entry in the PDI Strategy is when there's only one single FVG in the leg up or down.

Sometimes however you'll have moments where there's multiple FVG in the leg up or down, then you'll go to a higher timeframe to see if there's only one FVG, e.g on the 1 minute TF there's multiple ones but then there's only 1 in the 2 min. Because then you'll just have to wait for the 2 min FVG to get inversed and then you can enter.

If your bias is Bearish. You can then set partial TPs at the bottom of the accumulation zone and then have some runners to any other sellside that have been generated in the past.

You can even take that model if your bias is bullish, you just have to make sure to fully close once price reaches the bottom of the accumulation zone.

If we were Bullish the Set up would work the exact same way but just the other way around:

Something like this would be incredibly ideal if you were looking for a bearish PDI:
(S Tier Set up)

We have Equal lows at the bottom of the accumulation, we then have a IFVG near the peak of the manipulation, and then set the first TP at the bottom of the accumulation zone and then leave some runners if your bias is aligned with it.

This would be a S Tier set up for a Bullish PDI:

You could then have your TPs at the top of the accumulation zone or if it aligns with your bias leave some runners for targets that are higher up.

WHEN NOT TO TAKE

1. When the inversion close is too far from ideal entry
2. When time doesn't align
3. Against EQH or EQL
4. Respecting an opposing PD array

1 = If the Inversion is way too high, so near the highs or lows of the accumulation zone and it would give you terrible RR

2 = ldk

3 = Don't take it against EQH or EQL, they are kind of like magnets so why would you go against that?

4 = When you want to take a bearish PDI but you are inside a bullish 15 min FVG - don't take it, its very easy to get manipulated

Summary:

PDI PT 2

Often at the end of hourly candles volume starts to die out and liquidity starts forming. This liquidity comes in many forms such as simple Buy or Sell Side Liquidity or something like Equal Highs or Equal Lows, or something else.

We want Time to align with the way you want the price to move. Now let's say we don't even know our bias yet and we're approaching a new hourly open and we've been accumulating for a while. We now want to pay attention to how, for example 1 PM open? Is it going to seek the buyside or is it going to seek the sellside.

So If PDI forms at the end of an hourly candle and e.g the candle is OHLC and our manipulation is the wake up for that candle, we know that price has nowhere to go than down. Same goes for the other way around.

That's how you can catch really big moves.

What IS and what ISN'T a PDI?

All of these aren't valid PDI's

This is S-Tier

So let's say we're accumulating and a move up forms, how do we know that this is actually a manipulation? One of the ways is to look at equilibrium, once price taps into equilibrium we know that price has rebalanced and now after that happens we start seeing some rejection/retracement.

Here we have another example for a good manipulation, there's a unfilled 15 min FVG that has been left from before, price starts accumulating and then breaks out and taps into that FVG which then retraces into the FVG that was created in the leg down, that FVG gets inverse which gives us enough confirmation to long.

Generally speaking you want to know where you're trending in a range, once you break out of this range what PD Arrays are you hitting, what liquidity is being taken, etc. You just have to look at your left before the accumulation so that you know where the liquidity is laying

Here are some more examples of good setups:

You'll see something like this often

This is really really good but rarer to see,
